

How the $^{27}\text{Al}(n,\gamma)$ 7.72 MeV capture γ makes a SiPM $\wedge$ plastic leg (both deposit >0.5 MIP in one arm)

(1) Double Compton — the typical leg
 γ Compton-scatters in SiPM, the scattered γ Compton-scatters in plastic

(2) Pair production + EM shower — the high-energy leg
7.72 MeV γ converts (mostly in the Al capsule); $e^\pm$ spray both detectors

84%

of Al legs

16%

of Al legs
(higher energy)
